

LIN: Sovereign GPU AMM Settlement & Rollup Co-processor

Grant Proposal | Ethereum Foundation Ecosystem Support Program (ESP) | Requested: **\$30,000 USD**

1. Executive Summary & Core Innovation

DEX trading and batch settlement on Ethereum L1 face severe computational and economic limits. Re-executing thousands of state transitions across archival nodes to audit settlement integrity is slow and expensive. **LIN** introduces a sovereign, verified offload co-processor and parallel AMM settlement engine written in LIN (a deterministic numeric systems language) orchestrated by a pure C11 host runtime with a **strict execution runtime TCB of only 809 LOC** (zero LLVM/Zig dependency in production).

Running on commodity consumer hardware (AMD Radeon RX 6600, 28 CUs), our sovereign pipeline processes **2,000 Ethereum mainnet Uniswap v2 swaps in 1.7 milliseconds of kernel time** (1,176,000 swaps/sec kernel-only; 218 ms end-to-end cold wall-clock), enforces strict constant-product invariants ($x \cdot y \geq k$), filters routing deviations, and issues deterministic **canonical 208-byte LCR2 Merkle compute receipts**. These receipts enable client-side auditability in **~7.3 μ s per block (~3,200 $\times$ to 4,900 $\times$ cheaper than VM re-execution)**, with L1 root anchoring and inclusion proof verification implemented in contracts/LinReceiptVerifier.sol.

2. Empirical Performance: Real Mainnet Swaps Benchmark (AMD RX 6600)

Metric	Kernel Compute (GPU)	End-to-End Wall-Clock	Off-Chain Audit Advantage
Batch Throughput (N=2,000)	1,176,470 swaps/sec	9,166 swaps/sec (cold)	~3,200x faster than VM re-exec
Execution Time (N=2,000)	1.70 ms (0.85 μ s / swap)	218 ms (includes JIT/PCIe)	Receipt verified in ~7.3 μ s
Saturated Batch (N=10,000)	2.80 ms (3,300,000 swaps/s)	219 ms (45,000 swaps/s)	Amortizes cold startup latency
Trusted Computing Base (TCB)	809 LOC (core runtime)	6,628 LOC (full C0 toolchain)	Zero runtime heap / bounds-checked
Cryptographic Receipt	LCR2 208-byte canonical	SHA-256 Merkle root	O(1) client verification (hashlib)
On-Chain Bridge (Solidity)	Root anchor (settleBatch)	Spot inclusion proof	LinReceiptVerifier.sol verified

3. End-to-End Sovereign Architecture

- **Sovereign GPU Kernel (LIN OpenCL Emitter):** Written in pure LIN (src/lin_gpu_opengl_emitter.lin), emitting standards-compliant OpenCL C. Executes directly on physical AMD/Intel/Nvidia GPUs via dynamic loader (dlopen(libOpenCL.so)) without proprietary dependencies.
- **Deterministic Host VM (LinVM C0):** Pure C11 orchestration runtime (transpile/c/tool/lin_c0.c). Strict TCB: 809 LOC runtime, 6.6k LOC full toolchain. Emits canonical LCR2 Merkle receipts.
- **L1 On-Chain Verifier (Solidity):** contracts/LinReceiptVerifier.sol anchors batch Merkle roots and verifies both legacy and LCR2 inclusion proofs (verifyLCR2Inclusion).

4. Project Milestones & Budget (\$30,000 USD)

Milestone	Duration	Budget	Key Deliverables & Acceptance Criteria
Milestone 1: Production L1 Verifier Contract	4 Weeks	\$10,000	• Audited LinReceiptVerifier.sol supporting batched AMM state settlements. • Sepolia testnet deployment with automated verification scripts. • End-to-end integration test suite demonstrating <30k gas batch seals.
Milestone 2: Mempool Batcher & Daemon	6 Weeks	\$10,000	• Standalone daemon ingesting live Ethereum pending DEX transactions. • Real-time GPU streaming pipeline batching up to 10,000 swaps/second. • Automated emission of cryptographic receipts and IPFS/Arweave staging.
Milestone 3: Multi-GPU Portability & Formal Audit	4 Weeks	\$10,000	• Multi-vendor validation across AMD (ROCm), NVIDIA (CUDA/OpenCL), Apple Silicon. • Third-party smart contract security audit report. • Open-source developer SDK, reproducibility paper, and interactive live demo.

5. Public Goods Value & Open Source Commitment

All code, kernels, transpilation tools, and smart contracts are published under permissible open-source licenses (MIT / Apache-2.0). Any Ethereum builder, L2 rollup team, or DEX developer can freely clone the repository, run make benchmark-uniswap, and reproduce these results on consumer hardware in under 5 seconds. This grant directly strengthens Ethereum's decentralized scaling, validator efficiency, and computational auditability.
